

Ixodids in wild animals of the mountainous plateau Region of Santa Catarina State, Brazil

Ixodídeos em animais silvestres na Região do Planalto Serrano, Estado de Santa Catarina, Brasil

Marcia Sangaletti Lavina^{1*}; Antonio Pereira de Souza²;
Amélia Aparecida Sartor³; Anderson Barbosa de Moura³

Abstract

Knowledge of ixodids (hard ticks), as well as their ability to transmit pathogens to their hosts, and in some cases to humans, is significantly important for the establishment of epidemiological public health programs and surveillance. With the purpose of identifying ixodids from wild mammals in the mountainous plateau of Santa Catarina, we examined ticks collected or received in the Laboratory of Parasitology and Parasitic Diseases of the Centre of Agroveterinary Sciences (CAV/UDESC) from 2001 to 2011. The ixodids were collected from wild animals that were subjected to the screening process of the Veterinary Clinic Hospital (HCV) of CAV and from dead animals found on state highways. Using specific dichotomous keys, we identified *Amblyomma aureolatum* collected from *Pseudalopex gymnocercus*, *Lycalopex gymnocercus*, *Leoparduspardalis*, *Cerdocyon thous*, *Leopardus tigrinus*, *Puma concolor*, and *Bufo* sp.; *A. dubitatum* collected from *Hydrochoerus hydrochoeris*; *A. rotundatum* from *Puma concolor* and *Bohtrops* sp.; *A. ovale* from *Bufo* sp.; and *Rhipicephalus microplus* from *Mazama gouazoubira*. A specimen of *A. longirostre* was identified in an urban area house at the municipality of Lages. *A. rotundatum* that was collected from *Bohtrops* sp. and *Puma concolor*, and *A. longirostre* that was found in the environment, are reported for the first time in the state of Santa Catarina, Brazil.

Key words: *Amblyomma* spp., wild animals, ixodids, Santa Catarina

Resumo

O conhecimento da fauna de ixodídeos, bem como a potencialidade como transmissores de patógenos aos seus hospedeiros e em alguns casos aos humanos, é de grande importância para o estabelecimento de programas de saúde pública e vigilância epidemiológica. Com o objetivo de identificar ixodídeos de mamíferos silvestres no Planalto Serrano de Santa Catarina foram examinados carapatos, coletados ou recebidos no Laboratório de Parasitologia e Doenças Parásitárias do Centro de Ciências Agroveterinárias – CAV/UDESC no período 2001 a 2011. Os ixodídeos eram provenientes de animais silvestres que passaram pelo processo de triagem do Hospital de Clínicas Veterinárias (HCV) do CAV e de animais encontrados mortos em rodovias do Estado. De acordo com as chaves dicotómicas específicas identificou-se *Amblyomma aureolatum* coletados em *Pseudalopex gymnocercus*, *Lycalopex gymnocercus*, *Leoparduspardalis*, *Cerdocyon thous*, *Leopardus tigrinus*, *Puma concolor* e *Bufo* sp.; *A. dubitatum* em *Hydrochoerus hydrochoeris*; *A. rotundatum* em *Puma concolor* e *Bohtrops* sp.; *A. ovale*

em *Bufo* sp.; e *Rhipicephalus microplus* em *Mazama gouazoubira*. Foi identificado um exemplar de *A. longirostre* que se encontrava em uma residência da área urbana do município de Lages. As espécies *A. rotundatum* em *Bohtrops* sp. e em *Puma concolor*; e *A. longirostre*, encontrada no ambiente, foram relatadas pela primeira vez no estado de Santa Catarina, Brasil.

Palavras-chave: *Amblyomma* spp., animais silvestres, ixodídeos, Santa Catarina

Introduction

During the process of attachment and feeding, ticks are responsible for extensive damage to the host, including mechanical damage, trauma, despoiling, and toxic action. These arthropods are also responsible for transmitting pathogenic microorganisms through their saliva, which penetrates the host skin; this makes the ixodids the second vector group that most frequently transmits pathogens to humans, surpassed only by the Culicidae group of mosquitoes (MASSARD; FONSECA, 2004).

In this context, faunal surveys of ticks become an essential tool in recognizing and determining the occurrence of ticks, especially where there is interaction between wildlife and pets. According to Williams et al. (2002), controlling interactions between domestic and wild environments is the first step to estimate the risk of disease outbreaks.

According to Figueiredo et al. (2010), Brazil is one of the countries with the greatest biodiversity in the world, and to manage this living heritage, relevant strategies, plans, and programs must be established to ensure the sustainable use of available natural resources. The study of parasitic diseases and parasite-host interactions of wild animals, captive or free-living, is a key step in supporting conservation and preservation programs (CATÃO-DIAS, 2003). Tick species from domestic animals are the most studied, while species that parasitize wildlife are still poorly known, particularly in relation to taxonomy, biology, ecology, geographical distribution, their usual hosts, and their vector capacity as bioagents (BARROS-BATTESTI et al., 2006).

Materials and Methods

The mountainous plateau or sierra of Santa Catarina is a state region that includes the mesoregions of the west of Santa Catarina, the mountains, and part of the north of Santa Catarina. Many of the cities in the mountainous plateau are located over a thousand meters above sea level, and as a result during the winter months average temperatures do not exceed 10°C, with the presence of frost and the possibility of snow. The mountainous plateau region of Santa Catarina presents varying climatic characteristics, including harsh winters, mild springs and summers, and autumn with alternating temperatures between day and night periods (BACK et al., 2013).

According to the Köppen-Geiger classification, the climate of Santa Catarina receives the Cfa and Cfb designations. The first is subtropical with hot summers in which the temperature of the warmest month is higher than 22°C, and the second is the subtropical climate with mild summers. The Cfa climate belongs to the lower regions, while the Cfb occurs in areas of higher altitudes such as the mountainous plateau (MONTEIRO, 2001).

The vegetation of the mountainous plateau region is characterized by Araucaria forest comprising associations and groups of species with various names, including pine forest, pinewoods, pine zone, and Araucaria woodlands. The vegetation of this region also includes natural pasture areas composed of shrubs and grass, which are aimed at animal ranching.

In the period from 2001 to 2011, adult hard ticks were collected from ten different species of wild animals that underwent the screening process at the Veterinary Clinic Hospital (HCV) at the CAV and/

or were collected from dead animals on highways of the plateau region. The ixodids attached to wild mammals were found in the animals' skin by inspection and manually removed; subsequently, they were stored in bottles containing 70% alcohol identified with labels containing information about the host, place, and date of collection. The identification of adult instars was carried out under a stereomicroscope, according to the dichotomous key of Barros-Battesti et al. (2006).

This study was approved by the Ethics Committee of the institution (UDESC/CAV) where it was conducted.

Results and Discussion

In all, 173 adult ticks from five different species were identified, and these are presented, according to the host species, in Table 1. Among the tick-host associations found, it is worth mentioning *A. rotundatum* that was collected from *Bohtrops* sp., and the accidental parasitism of *Puma concolor*. In regard to *A. longirostre* found in the environment, this is the first report of this species in the Santa Catarina State, Brazil.

Table 1. Number of adult ixodid parasites of wild animals collected and identified in some municipalities of the mountainous plateau of Santa Catarina State.

Host	Location	Number of collected Ectoparasites	Identified Ectoparasites
<i>Leopardus tigrinus</i>	Lages	01	<i>Amblyomma aureolatum</i>
<i>Hydrochoerus hydrochoeris</i>	São José do Cerrito	94	<i>Amblyomma dubitatum</i>
<i>Bufo</i> sp.	Lages	02	<i>Amblyomma aureolatum</i>
<i>Bufo</i> sp.	Lages	02	<i>Amblyomma ovale</i>
<i>Puma concolor</i>	Curitibanos	18	<i>Amblyomma aureolatum</i>
<i>Puma concolor</i>	Lages	10	<i>Amblyomma aureolatum</i>
<i>Puma concolor</i>	Campo Belo do Sul	01	<i>Amblyomma rotundatum</i>
<i>Cerdocyon thous</i>	Bom Retiro	16	<i>Amblyomma aureolatum</i>
<i>Cerdocyon thous</i>	Lages	05	<i>Amblyomma aureolatum</i>
<i>Mazama gouazoubira</i>	Lages	13	<i>Rhipicephalus microplus</i>
<i>Pseudalopex gymnocercus</i>	Lages	08	<i>Rhipicephalus microplus</i>
<i>Lycalopex gymnocercus</i>	Lages	01	<i>Amblyomma aureolatum</i>
<i>Leopardus pardalis</i>	Lages	01	<i>Amblyomma aureolatum</i>
<i>Bohtrops</i> sp.	Lages	01	<i>Amblyomma rotundatum</i>
Total		173	

The species identified were as follows: *A. aureolatum* collected from ocelot (*Leopardus pardalis*), toad (*Bufo* sp.), pampas fox (*Lycalopex gymnocercus*), crab-eating fox (*Cerdocyon thous*), oncilla (*Leopardus tigrinus*), puma (*Puma concolor*), and pampas fox (*Pseudalopex gymnocercus*); *A. rotundatum* from snake (*Bohtrops* sp.) and puma (*Puma concolor*); *R. microplus* from pampas fox and gray brocket deer (*Mazama gouazoubira*); *A.*

ovale from toad; and *A. dubitatum* from capybara (*Hydrochoerus hydrochoeris*).

According to Barros-Battesti et al. (2006), *A. aureolatum* and *A. ovale* are closely related species that in the adult phase are parasites of carnivores, the later species also reaching to other species such as procyonids and mustelids (LABRUNA et al., 2005). In Santa Catarina State, we identified *A. aureolatum* in wild felines and canines; and

its presence in oncilla confirms the occurrence of ixodids in wild felines of Santa Catarina. Martins et al. (2010) also recorded parasitism by this species in margays (*Leopardus wiedii*), in the metropolitan region of Porto Alegre, Rio Grande do Sul State.

Specimens of *A. aureolatum* found in the crab-eating fox were also reported by Rodrigues and Daemon (2004), who observed the presence of the species in *Cerdocyon thous* coming from the “Zona da Mata” of Minas Gerais State. According to Aragão and Fonseca (1961), the species is regularly found in the wild animals of dog-inhabited areas, especially wild canines and felines.

In the northern region of Santa Catarina the species *A. aureolatum* and *A. ovale* were reported in monkeys in the cities of Indaiá, Blumenau, Garuva, and Jaraguá do Sul (LAVINA et al., 2011), climate region Cfa, which indicates that this species is well adapted to the Santa Catarina climate, with its variations in Cfa or Cfb.

The infestation of frogs by adult ticks of *A. aureolatum* and *A. ovale* is considered an extremely unusual parasitism, primarily because amphibians are not the preferred hosts of these species. Secondly, because in this study, *A. ovale* has not been reported with expression in carnivores, the hosts might have contributed to an accidental parasitism of *A. ovale* in *Bufo* spp. Unusual parasitism of frogs has been reported by other authors, such as Sinkoc and Brum (1997), who recorded the presence of *A. fuscum* and *A. humerale* in *Bufo arenalis* in São Paulo State. At the time, the account given by those authors featured a new host and a new geographic location for both species. Guglielmone et al. (2003) studied *A. aureolatum* and *A. ovale* and reported the presence of a male *A. ovale* in a toad. Luz and Faccini (2013), in a review of parasitism of frogs by ticks in Brazil, described *A. dissimile* and *A. rotundatum* as the most common species in these animals, despite the large number of species of ticks. The authors also reported the presence of *A. fuscum*, *A. goeldii*, *A. humerale*, and *A. sculptum* in frogs, in particular

those belonging to the genus *Rhinella*; and since *A. sculptum* is considered exclusively parasitic in warm-blooded animals such as mammals and birds, the authors consider this case to be a totally accidental parasitism. Robinson (1926) had already reported *Bufo marinus* as a host for *A. sculptum* (a species of the *A. cajennense* complex), *A. dissimile*, and *A. goeldii*; and *Bufo* sp. as a host of *A. goeldii* and *A. rotundatum*.

In *Rhinella schneideri* in the state of Paraná, Antonucci et al. (2011) recorded the presence of *A. rotundatum*, and Ahid et al. (2009) made the first report of the species parasitizing frogs in Mossoró, Rio Grande do Norte State.

The species *A. rotundatum* was found parasitizing snake and puma in Florianópolis, Santa Catarina State, by Aragão (1936), but that author did not mention the species of the host. The parasitism found in puma can be considered an accidental parasitism as amphibians and reptiles are usual hosts for this species of hard tick. A female *A. rotundatum* was identified on a snake (*Bothrops* sp.), confirming the work of Brum and Costa (2003) who identified *A. rotundatum* in the crossed pit viper (*Bothrops alternatus*) in the south region of the municipality of Pelotas, Brazil.

Labruna et al. (2002) also identified *A. rotundatum* in *Bothrops moojeni* (Brazilian lance head) and *Boa constrictor* (“jibóia”), and Figueiredo et al. (2010) found adults of the same species in *Boa constrictor* and *Iguana*.

This current record of *R. microplus* parasitizing *Pseudalopex gymnocercus* and *Mazama gouazoubira* reinforces previous findings in the literature that this tick species can parasitize other host species that, even if temporarily, share the same cattle infested pasture (LABRUNA et al., 2005). Under these conditions it has been described in other animals such as the marsh deer (*Blastocerus dichotomus*) (SZABÓ et al., 2003) and the white lipped peccary (ITO et al., 1998). The participation of these hosts in maintaining this tick species in

the environment appears to be more important than might be expected, to the point that Graham and Hourigan (1977) reported that in the United States, *R. microplus* was considered eradicated in 1943 through the chemical control and management of the white-tailed deer population (*Odocoileus virginianus*). In 1952, in Puerto Rico, through chemical control and elimination of the deer population on the island, as well as in New Guinea, *R. microplus* was eradicated (PEREIRA, 2008).

Present from north to south in South America, *A. dubitatum* has been reported in Brazil in states in the southeast, south, and midwest (CAMARGO-NEVES, 2004). It was the only species found parasitizing capybaras, but the number of samples collected for this host was only three. In Lages, Quadros et al. (2013) found adults of *A. sculptum* (a species belonging to the *A. cajennense* complex) and nymphs of *A. dubitatum* in capybaras run over on a highway. According to Famadas et al. (1997), although the capybaras are considered primary hosts for all parasitic stages (larva, nymph, and adult) of the *A. dubitatum* tick, the larva and nymph stages have lower parasitic specificity and can feed on different host species, including humans.

The observation of *A. longirostre* in our study in a house in the Lages municipality urban area may be explained by the fact that the species in its immature stage parasitizes birds, especially wild birds, and so can be dispersed by them to other environments where mammals belonging to the order Rodentia are the main hosts for the adult stage of this species (BARROS-BATTESTI et al., 2006).

Teixeira et al. (2008), in a study of wild birds' ticks of the Sorocaba Zoo in São Paulo State, found *A. longirostre* in the ruby-crowned tanager (*Tachyphonus coronatus*), in the red-legged seriema (*Cariama cristata*), and in the peacock (*Pavo cristatus*). Labruna et al. (2002) found *A. longirostre* in Brazilian porcupine (*Coendou prehensilis*), and Silveira et al. (2008) found *A. longirostre* in the black urchin (*Chaetomys subspinosus*). In Brazil,

the species is well established in the states of Paraná, Santa Catarina, Rio Grande do Sul, São Paulo, Rio de Janeiro, Minas Gerais, Goiânia, Pernambuco, Acre, Amazonas, Pará, and Rondônia (ARZUA et al., 2005; GUIMARÃES et al., 2001).

Conclusions

To our knowledge, this is the first report of *A. rotundatum* in *Bohtrops* sp. in Santa Catarina and the first record of *A. longirostre* in the state. We believe that the findings of our study contribute to knowledge of the parasitic fauna of wild animals, establishing new areas of occurrence and clarifying the geographical distribution of ectoparasites, especially in poorly studied places such as the state of Santa Catarina.
